

Write the PHP script to create an application to convert temperature from one unit of measurement to another. The application must consist of a Web form to accept the temperature in a unit, such as Centigrade or Fahrenheit. In addition, the Web form should contain a set of radio buttons to specify the unit of the temperature, input by the user. When the user clicks the Convert button, the PHP script must retrieve the unit and the input temperature from the radio button and the text box, respectively, and display the temperature in a different unit.
